SPHOORTHY ENGINEERING COLLEGE

An Autonomous Institution Approved by AICTE & Accredited with NAAC Grade 'A'
Department of Examination & Academic Affairs · Hyderabad — 501510

Digital Signal Processing: DFT, FFT Algorithms, IIR & FIR Filter Design

Program / Dept: B.Tech / MBA — ECE	**Course Code / Title:** Digital Signal Processing (EC501PC)
Academic Regulation: Autonomous (SR23 / SR24)	**Curriculum Semester:** Semester 5 (Year 3)
Credits / Contact Hours: 3 Credits · 48 Lecture Hours	**Evaluation Scheme:** Continuous Internal (40M) + End Sem (60M)

Course Overview & Pedagogical Objectives:

Discrete Fourier Transform (DFT), Radix-2 FFT algorithms (DIT and DIF), IIR filter design (Butterworth, Chebyshev), FIR filter design using Windows, and DSP processors. The primary objective of this course is to equip students with sound theoretical rigor, analytical problem-solving competencies, and real-world system engineering capabilities demanded by premier technological organizations and competitive graduate benchmarks.

Course Outcomes (COs) & Bloom's Taxonomy Mapping:

CO ID	Course Learning Outcome Description	Bloom's Level
CO 1	Understand and formulate fundamental concepts of Unit 1: Discrete Fourier Transform (DFT).	L2 Understand
CO 2	Analyze algorithms, mechanisms, and models in Unit 2: Fast Fourier Transform (FFT) Algorithms.	L4 Analyze
CO 3	Design and evaluate robust architectures for Unit 3: IIR Digital Filter Design.	L5 Evaluate
CO 4	Implement and optimize operational pipelines in Unit 4: FIR Digital Filter Design.	L3 Apply
CO 5	Integrate state-of-the-art frameworks in Unit 5: Digital Filter Realization & Quantization for industrial solutions.	L6 Create

Comprehensive Module Index:

Unit	Title & Core Concepts	Page
Unit 1	**Unit 1: Discrete Fourier Transform (DFT)**: Properties of DFT, Circular convolution, Linear convolution using DFT, Circular correlation, and Fast convolut...	Page 2
Unit 2	**Unit 2: Fast Fourier Transform (FFT) Algorithms**: Radix-2 Decimation-In-Time (DIT) FFT, Decimation-In-Frequency (DIF) FFT, Butterfly signal flow graphs, and Com...	Page 3
Unit 3	**Unit 3: IIR Digital Filter Design**: Analog filter approximations (Butterworth, Chebyshev Type I), Impulse Invariance Method, Bilinear Transformati...	Page 4
Unit 4	**Unit 4: FIR Digital Filter Design**: Linear phase conditions of FIR filters, Symmetric and anti-symmetric impulse response, Windowing design techni...	Page 5

Unit 5	**Unit 5: Digital Filter Realization & Quantization**: Direct Form I and II, Cascade, and Parallel realizations of IIR systems, Transversal and Linear phase FIR real...	Page 6

UNIT 1: DISCRETE FOURIER TRANSFORM (DFT) • *Core Theory & Practice Guide*

1.1 Technical Exposition & Conceptual Foundations

The study of unit 1: discrete fourier transform (dft) forms an indispensable cornerstone of Digital Signal Processing (EC501PC). Specifically, Properties of DFT, Circular convolution, Linear convolution using DFT, Circular correlation, and Fast convolution methods (Overlap-Add, Overlap-Save). Modern applications require deep awareness of edge conditions, invariant properties, and trade-offs between computational throughput, latency overhead, memory footprint, and architectural scalability.

In university examinations and practical engineering systems, solutions must be formulated with mathematical clarity. Each sub-mechanism must satisfy safety, liveness, and fault-tolerance constraints while adhering to standard autonomous syllabus requirements.

1.2 Architectural Principles & Comparative Analysis

Component / Topic	Key Mechanism & Principle	Operational Trade-off
Theoretical Model	Formal representation of Unit 1 entities and lifecycle stages.	Higher mathematical abstraction vs implementation friction.
Algorithmic Engine	State machine transitions, recurrence guarantees, and verification steps.	Time complexity bounds vs memory consumption.
Real-World Systems	Deployment in enterprise distributed systems and contemporary toolchains.	Fault-tolerant redundancy vs network overhead.

1.3 Practical Formulation & Execution Workflow

```
// Standard Implementation Outline & Pseudocode for Unit 1
1. Initialize system data structures and state variables under initial constraints.
2. Execute continuous invariant checking across state boundaries.
3. Apply optimization bounds: O(log N) average time or amortized linear bounds.
4. Catch boundary failure cases (underflow, overflow, concurrency race, null references).
5. Commit verified state or invoke transactional rollback upon validation failure.
```

1.4 Autonomous End-Semester Examination Question Bank

Type	Question & Expected Technical Answer Outline	Marks
Part A	**Q1:** Define the primary objective of Unit 1 and state two essential real-world applications. • *Expected: Exact definition, mathematical constraint formulation, and dual industry examples.*	**2 M**
Part A	**Q2:** Differentiate between static vs dynamic formulations of key mechanisms in Unit 1. • *Expected: 2-column comparison table covering memory, allocation time, and failure recovery.*	**2 M**
Part B	**Q3:** Explain the complete working architecture of Unit 1 with neat functional block diagrams and step-by-step algorithmic trace. • *Expected: Labeled diagram (3M), mathematical derivation (3M), algorithm steps (2M), complexity analysis (2M).*	**10 M**
Part B	**Q4:** Analyze the worst-case, best-case, and average-case performance bounds for processes in Unit 1 with worked numerical example. • *Expected: Step-by-step problem solution, boundary checks, and conclusive optimality proof.*	**10 M**

UNIT 2: FAST FOURIER TRANSFORM (FFT) ALGORITHMS • *Core Theory & Practice Guide*

2.1 Technical Exposition & Conceptual Foundations

The study of unit 2: fast fourier transform (fft) algorithms forms an indispensable cornerstone of Digital Signal Processing (EC501PC). Specifically, Radix-2 Decimation-In-Time (DIT) FFT, Decimation-In-Frequency (DIF) FFT, Butterfly signal flow graphs, and Computational complexity reduction from O(N^2) to O(N log N). Modern applications require deep awareness of edge conditions, invariant properties, and trade-offs between computational throughput, latency overhead, memory footprint, and architectural scalability.

In university examinations and practical engineering systems, solutions must be formulated with mathematical clarity. Each sub-mechanism must satisfy safety, liveness, and fault-tolerance constraints while adhering to standard autonomous syllabus requirements.

2.2 Architectural Principles & Comparative Analysis

Component / Topic	Key Mechanism & Principle	Operational Trade-off
Theoretical Model	Formal representation of Unit 2 entities and lifecycle stages.	Higher mathematical abstraction vs implementation friction.
Algorithmic Engine	State machine transitions, recurrence guarantees, and verification steps.	Time complexity bounds vs memory consumption.
Real-World Systems	Deployment in enterprise distributed systems and contemporary toolchains.	Fault-tolerant redundancy vs network overhead.

2.3 Practical Formulation & Execution Workflow

```
// Standard Implementation Outline & Pseudocode for Unit 2
1. Initialize system data structures and state variables under initial constraints.
2. Execute continuous invariant checking across state boundaries.
3. Apply optimization bounds: O(log N) average time or amortized linear bounds.
4. Catch boundary failure cases (underflow, overflow, concurrency race, null references).
5. Commit verified state or invoke transactional rollback upon validation failure.
```

2.4 Autonomous End-Semester Examination Question Bank

Type	Question & Expected Technical Answer Outline	Marks
Part A	**Q1:** Define the primary objective of Unit 2 and state two essential real-world applications. • *Expected: Exact definition, mathematical constraint formulation, and dual industry examples.*	**2 M**
Part A	**Q2:** Differentiate between static vs dynamic formulations of key mechanisms in Unit 2. • *Expected: 2-column comparison table covering memory, allocation time, and failure recovery.*	**2 M**
Part B	**Q3:** Explain the complete working architecture of Unit 2 with neat functional block diagrams and step-by-step algorithmic trace. • *Expected: Labeled diagram (3M), mathematical derivation (3M), algorithm steps (2M), complexity analysis (2M).*	**10 M**
Part B	**Q4:** Analyze the worst-case, best-case, and average-case performance bounds for processes in Unit 2 with worked numerical example. • *Expected: Step-by-step problem solution, boundary checks, and conclusive optimality proof.*	**10 M**

UNIT 3: IIR DIGITAL FILTER DESIGN • *Core Theory & Practice Guide*

3.1 Technical Exposition & Conceptual Foundations

The study of unit 3: iir digital filter design forms an indispensable cornerstone of Digital Signal Processing (EC501PC). Specifically, Analog filter approximations (Butterworth, Chebyshev Type I), Impulse Invariance Method, Bilinear Transformation Method (BTM), Warping effect, and Pre-warping. Modern applications require deep awareness of edge conditions, invariant properties, and trade-offs between computational throughput, latency overhead, memory footprint, and architectural scalability.

In university examinations and practical engineering systems, solutions must be formulated with mathematical clarity. Each sub-mechanism must satisfy safety, liveness, and fault-tolerance constraints while adhering to standard autonomous syllabus requirements.

3.2 Architectural Principles & Comparative Analysis

Component / Topic	Key Mechanism & Principle	Operational Trade-off
Theoretical Model	Formal representation of Unit 3 entities and lifecycle stages.	Higher mathematical abstraction vs implementation friction.
Algorithmic Engine	State machine transitions, recurrence guarantees, and verification steps.	Time complexity bounds vs memory consumption.
Real-World Systems	Deployment in enterprise distributed systems and contemporary toolchains.	Fault-tolerant redundancy vs network overhead.

3.3 Practical Formulation & Execution Workflow

```
// Standard Implementation Outline & Pseudocode for Unit 3
1. Initialize system data structures and state variables under initial constraints.
2. Execute continuous invariant checking across state boundaries.
3. Apply optimization bounds: O(log N) average time or amortized linear bounds.
4. Catch boundary failure cases (underflow, overflow, concurrency race, null references).
5. Commit verified state or invoke transactional rollback upon validation failure.
```

3.4 Autonomous End-Semester Examination Question Bank

Type	Question & Expected Technical Answer Outline	Marks
Part A	**Q1:** Define the primary objective of Unit 3 and state two essential real-world applications. • *Expected: Exact definition, mathematical constraint formulation, and dual industry examples.*	**2 M**
Part A	**Q2:** Differentiate between static vs dynamic formulations of key mechanisms in Unit 3. • *Expected: 2-column comparison table covering memory, allocation time, and failure recovery.*	**2 M**
Part B	**Q3:** Explain the complete working architecture of Unit 3 with neat functional block diagrams and step-by-step algorithmic trace. • *Expected: Labeled diagram (3M), mathematical derivation (3M), algorithm steps (2M), complexity analysis (2M).*	**10 M**
Part B	**Q4:** Analyze the worst-case, best-case, and average-case performance bounds for processes in Unit 3 with worked numerical example. • *Expected: Step-by-step problem solution, boundary checks, and conclusive optimality proof.*	**10 M**

UNIT 4: FIR DIGITAL FILTER DESIGN • *Core Theory & Practice Guide*

4.1 Technical Exposition & Conceptual Foundations

The study of unit 4: fir digital filter design forms an indispensable cornerstone of Digital Signal Processing (EC501PC). Specifically, Linear phase conditions of FIR filters, Symmetric and anti-symmetric impulse response, Windowing design techniques (Rectangular, Hamming, Hanning, Blackman). Modern applications require deep awareness of edge conditions, invariant properties, and trade-offs between computational throughput, latency overhead, memory footprint, and architectural scalability.

In university examinations and practical engineering systems, solutions must be formulated with mathematical clarity. Each sub-mechanism must satisfy safety, liveness, and fault-tolerance constraints while adhering to standard autonomous syllabus requirements.

4.2 Architectural Principles & Comparative Analysis

Component / Topic	Key Mechanism & Principle	Operational Trade-off
Theoretical Model	Formal representation of Unit 4 entities and lifecycle stages.	Higher mathematical abstraction vs implementation friction.
Algorithmic Engine	State machine transitions, recurrence guarantees, and verification steps.	Time complexity bounds vs memory consumption.
Real-World Systems	Deployment in enterprise distributed systems and contemporary toolchains.	Fault-tolerant redundancy vs network overhead.

4.3 Practical Formulation & Execution Workflow

```
// Standard Implementation Outline & Pseudocode for Unit 4
1. Initialize system data structures and state variables under initial constraints.
2. Execute continuous invariant checking across state boundaries.
3. Apply optimization bounds: O(log N) average time or amortized linear bounds.
4. Catch boundary failure cases (underflow, overflow, concurrency race, null references).
5. Commit verified state or invoke transactional rollback upon validation failure.
```

4.4 Autonomous End-Semester Examination Question Bank

Type	Question & Expected Technical Answer Outline	Marks
Part A	**Q1:** Define the primary objective of Unit 4 and state two essential real-world applications. • *Expected: Exact definition, mathematical constraint formulation, and dual industry examples.*	**2 M**
Part A	**Q2:** Differentiate between static vs dynamic formulations of key mechanisms in Unit 4. • *Expected: 2-column comparison table covering memory, allocation time, and failure recovery.*	**2 M**
Part B	**Q3:** Explain the complete working architecture of Unit 4 with neat functional block diagrams and step-by-step algorithmic trace. • *Expected: Labeled diagram (3M), mathematical derivation (3M), algorithm steps (2M), complexity analysis (2M).*	**10 M**
Part B	**Q4:** Analyze the worst-case, best-case, and average-case performance bounds for processes in Unit 4 with worked numerical example. • *Expected: Step-by-step problem solution, boundary checks, and conclusive optimality proof.*	**10 M**

UNIT 5: DIGITAL FILTER REALIZATION & QUANTIZATION • *Core Theory & Practice Guide*

5.1 Technical Exposition & Conceptual Foundations

The study of unit 5: digital filter realization & quantization forms an indispensable cornerstone of Digital Signal Processing (EC501PC). Specifically, Direct Form I and II, Cascade, and Parallel realizations of IIR systems, Transversal and Linear phase FIR realization, Finite word-length quantization effects. Modern applications require deep awareness of edge conditions, invariant properties, and trade-offs between computational throughput, latency overhead, memory footprint, and architectural scalability.

In university examinations and practical engineering systems, solutions must be formulated with mathematical clarity. Each sub-mechanism must satisfy safety, liveness, and fault-tolerance constraints while adhering to standard autonomous syllabus requirements.

5.2 Architectural Principles & Comparative Analysis

Component / Topic	Key Mechanism & Principle	Operational Trade-off
Theoretical Model	Formal representation of Unit 5 entities and lifecycle stages.	Higher mathematical abstraction vs implementation friction.
Algorithmic Engine	State machine transitions, recurrence guarantees, and verification steps.	Time complexity bounds vs memory consumption.
Real-World Systems	Deployment in enterprise distributed systems and contemporary toolchains.	Fault-tolerant redundancy vs network overhead.

5.3 Practical Formulation & Execution Workflow

```
// Standard Implementation Outline & Pseudocode for Unit 5
1. Initialize system data structures and state variables under initial constraints.
2. Execute continuous invariant checking across state boundaries.
3. Apply optimization bounds: O(log N) average time or amortized linear bounds.
4. Catch boundary failure cases (underflow, overflow, concurrency race, null references).
5. Commit verified state or invoke transactional rollback upon validation failure.
```

5.4 Autonomous End-Semester Examination Question Bank

Type	Question & Expected Technical Answer Outline	Marks
Part A	**Q1:** Define the primary objective of Unit 5 and state two essential real-world applications. • *Expected: Exact definition, mathematical constraint formulation, and dual industry examples.*	**2 M**
Part A	**Q2:** Differentiate between static vs dynamic formulations of key mechanisms in Unit 5. • *Expected: 2-column comparison table covering memory, allocation time, and failure recovery.*	**2 M**
Part B	**Q3:** Explain the complete working architecture of Unit 5 with neat functional block diagrams and step-by-step algorithmic trace. • *Expected: Labeled diagram (3M), mathematical derivation (3M), algorithm steps (2M), complexity analysis (2M).*	**10 M**
Part B	**Q4:** Analyze the worst-case, best-case, and average-case performance bounds for processes in Unit 5 with worked numerical example. • *Expected: Step-by-step problem solution, boundary checks, and conclusive optimality proof.*	**10 M**
